Cyclopropenone

ABSTRACT

The reaction of cyclic imines (1-pyrrolines and piperideines) with a cyclopropenone leads to pyrrolizidines and indolizidines, respectively, each with a hydroxy group on the carbon atom at the bridgehead. The cyclopropenone functions as an all-carbon 1,3-dipole equivalent towards the cyclic imine in this reaction, and the cyclic imines used include polyhydroxylated systems, thus allowing access to australine, alexine and hyacinthacine type compounds. The pyrrolizidine products contain the core of the jenamidine and bohemiaamine natural products, which are of interest as cell-proliferation inhibitors and cell–cell adhesion inhibitors.

© 2012 Elsevier Ltd. All rights reserved.

The pyrrolizidine¹ and indolizidine^{1b,2} heterocycles attract significant attention due to their biological activity, and the synthetic challenges that they present.^{1,2} Typical compounds, shown in Figure 1, are natural iminosugars such as hyacinthacines A₁/A₂ (1),³ hyacinthacines B₁/B₂ (2),⁴ australine (3) (and its bridgehead epimer alexine)⁵ and castanospermine (4),⁶ which have attracted interest as glycosidase inhibitors. Glycosidases play important roles in a number of diseases including many cancers, lysosomal storage disorders such as Gaucher's disease, and type II diabetes.⁷ Iminosugars have also gained interest as antiviral compounds and antibiotics.⁷ Also of importance are indolizidine alkaloids with alkyl substituents, such as the amphibian derived indolizidine 195B (5),⁸ and related systems.^{1b,9} These continue to attract interest as, for example, inhibitors of nicotinic receptor-channels and neuromuscular transmission. Of particular interest to our work are pyrrolizidines such as bohemiaamine (6)¹⁰ and the related depoxidised NP25302,¹¹ a rare pyrrolizidin-1-one sub-class isolated from *Actinosporangium* sp. and from marine *Streptomyces* sp., members of which have shown significant cell–cell adhesion inhibitory activity. The structurally related fungal derived pyrrolizin-1-ols, epohelmins A and B (7)¹² are lanosterol synthase inhibitors. Of great relevance to the work reported in this Letter are systems that have a hydroxy group on the carbon atom at the bridgehead such as the antitumour, antibiotic and antiviral clazamycins A and B (8),¹³ jenamidines B₁/B₂ (9b) and C (10),^{11a,14} and the synthetic

8a-hydroxy-indolizidines.¹⁵ Jenamidine A₁/A₂ (9a) inhibits proliferation of leukaemia cell line K-562 with a reported GI₅₀ of 1.9 µg/mL.^{11a,14}

Scheme 1. Synthesis of hydroxy-pyrrolizidines and indolizidines.

In this Letter, we describe a new synthesis of bridgehead (**7a**- and **8a**-) hydroxy-substituted pyrrolizidines and indolizidines (**14**) (see Scheme 1) from the reaction of cyclic imines **11** ($n = 1$ or 2) with cyclopropanones **12**, a process that we believe proceeds through the rapid aerial oxidation of a transient intermediate **13**.

The reaction of cyclic imines with cyclopropanones is a process that we have studied previously using cyclic imines **15** that are 2-substituted ($X = O, S$; $R = \text{Me, Et}$),¹⁶ and we have shown that a range of alkoxy- and alkylthio-substituted cyclic imines react to give bicyclic systems **16** in the azetidinopyrrole ($n = 0$), pyrrolizidine ($n = 1$), indolizidine ($n = 2$) and pyrroloazepine ($n = 3$) classes, as summarised in Scheme 2.

In order to produce compounds with a bridgehead hydrogen, a feature common to natural products **1–5**, **7** and **9a**, we sought to explore the reactions of 2-unsubstituted cyclic imines with cyclopropanones, and report the results of this study herein. We began our study with the synthesis of the imines **17–21** shown in Figure 2, with the ultimate goal of natural product syntheses.

Imine **17** was selected to allow, after reaction with an appropriate cyclopropanone, direct access to analogues **13** (see Scheme 1) of the jenamidines (**9a**) and, after manipulation of the enone functionality and/or side-chains, access to jenamidines **A₁/A₂** themselves. Imine **17** was accessed by cyclisation of 4-aminobutyraldehyde diethyl acetal which was stabilised as its zinc iodide complex.¹⁷ Imine **18** was chosen ultimately to explore access to hyacinthacines **B₁/B₂** (**2**), but also to a range of potentially interesting hydroxymethyl pyrrolizidines, and we synthesised it as a single enantiomer using an aza-Wittig based route starting from *L*-glutamic acid, exactly as described by Banfi et al.¹⁸ Imines **19**¹⁹ and **20**²⁰ were chosen as they offer a potential route into indolizidines such as **5** and analogues, and these imines were made by an adaptation of reported *N*-chlorination-dehydrochlorination sequences.^{19,20} Imine **21** was chosen due to its ready availability²¹ and its potential to allow access to polyhydroxylated pyrrolizidines, including hyacinthacine **A₂** (**1**) and australine (**3**) and/or their epimers, after pyrrolidinone reduction and benzyl deprotection.

With imines **17–21** synthesised as described,^{17–21} we started to explore their reactivity towards diphenylcyclopropanone (**12a**; $R^1 = R^2 = \text{Ph}$), phenylcyclopropanone (**12b**; $R^1 = \text{H}$, $R^2 = \text{Ph}$) and cyclopropanone (**12c**; $R^1 = R^2 = \text{H}$). Diphenylcyclopropanone is commercially available, whilst phenylcyclopropanone^{16c,22} and cyclopropanone²³ were synthesised as described in the literature. Cyclopropanones have attracted recent interest as all-carbon 1,3-dipole equivalents,^{16,24} as alkyne precursors in click processes,²⁵ and as novel catalytic platforms.²⁶ The first cyclopropanone reactions performed in our current study, as shown in Scheme 3, were those of imines **17** and **20** (the most readily available) with commercially available diphenylcyclopropanone (**12a**). These two

Scheme 2. The use of 2-substituted cyclic imines.

Scheme 3. Synthesis of **7a**-/**8a**-hydroxy-indolizidines and pyrrolizidines.

reactions occurred extremely smoothly, but we were surprised to discover an extra 16 mass units in the mass spectra of the products. This, together with the absence of a C–H signal (the expected bridgehead C–H) in each of the ¹³C and ¹H NMR spectra, the presence of an additional quaternary carbon (¹³C) and a clear OH in the infra-red and ¹H NMR spectra, led us to believe that the products that had formed were the alcohols **14a** and **14b**, rather than the expected compounds **13a** and **13b**.²⁷ Alcohols **14a** and **14b** were isolated in 61% and 84% yields, respectively. Compound **14a** was crystalline and found to be suitable for study by X-ray crystallography (Fig. 3),²⁸ which confirmed that the structure was that deduced. We assume that the expected adducts **13**, via their enol tautomers **22**, are unusually susceptible to aerial oxidation, and

Figure 3. X-ray crystallographic structure (ORTEP) of compound **14a**.

Table 17a-/8a-Hydroxy-indolizidines and pyrrolizidines from cyclopropanones **12** and imines **17–21**²⁷

Product	n	Imine	12 , R ¹ and R ²	Yield (%)
14a	1	17	R ¹ = R ² = Ph	61
14b	2	19	R ¹ = R ² = Ph	84
14c	1	17	R ¹ = H, R ² = Ph	26
14d	2	19	R ¹ = H, R ² = Ph	57
14e	1	18	R ¹ = H, R ² = Ph	36
14f	1	18	R ¹ = R ² = H	30
14g	1	18	R ¹ = R ² = Ph	37
14h	2	20	R ¹ = R ² = H	33
14i	1	21	R ¹ = R ² = H	34

that the initial product of oxidation, the hydroperoxide **23** (Scheme 3), undergoes O–O cleavage to form the isolated alcohols **14**. It is known that enols and their derivatives can undergo easy oxidation to α -hydroxy ketones²⁹ even in the absence of catalyst, photosensitiser or photoinducer.³⁰ Similarly, 3-hydroxypyrroles have been shown to undergo photooxidation to give highly reactive hydroperoxides which are easily intercepted in synthetically useful processes,³¹ lending further credence to the involvement of species **22/23**. We cannot rule out the possibility that cyclopropanones, cyclic enaminones or their hydroxypyrrole tautomers, behave as photosensitisers or photoinducers. In other catalyst-free aerobic oxidation systems involving enols, it has been noted that free-radical traps fail to halt the reaction or give ESR signals, and that intermediate peroxides can be detected.³⁰ It is also possible that intermediate **23** acts as an oxidising agent towards compound **22** in order to produce the final product **14**.³² Further mechanistic studies on this aspect are underway in our laboratory.

Other imines and cyclopropanones behaved in the same manner and the results are summarised in Table 1.²⁷ Imines **17**, **18** and **19** reacted with phenylcyclopropanone to give compounds **14c**, **14d** and **14e** as single regioisomers (R¹ = H, R² = Ph; easily identified by HMBC), presumably due to the attack of the cyclopropanone **12** by the imine at the least hindered carbon, as we previously observed when working with this and other mono-substituted cyclopropanones.¹⁶ With imines **18**, **20** and **21**, the products **14e–i** were isolated as single diastereoisomers. Each of the pyrrolizidines **14e–g** showed the CH₂OTBDMS and OH groups to be *cis* to each other (NOESY). We were unable to determine the relative stereochemistry in indolizidine **14h**, but by analogy to that observed in compounds **14e–g**, we have tentatively assigned the OH and Me groups as *cis* to each other. Pyrrolizidine **14i** was formed from the chiral pool derived enantiopure²¹ imine **21**. The stereochemistry of the new stereocentre—the bridgehead OH—was established by NOESY which showed OH to be *cis* to the adjacent OBn and *cis* to the CH₂OBn group, and also confirmed the relative stereochemistry of the other chiral centres. In the case of compound **14i**, the enol **22** was the initial isolated product but underwent quantitative conversion (CDCl₃, NMR tube) into the 7a-hydroxypyrrolizidine **14i** over 24 h. Whilst this is significant in terms of the proposed mechanism in Scheme 3, this was the only system where we were able to observe enol formation. The use of imine **21** has allowed us to produce systems that are closely related to the hyacinthacine, australine and alexine natural products (**1–3**). The 7a-hydroxypyrrolizidines **14** (n = 1) produced from the pyrrolines **17**, **18** and **21** have a core structure that is closely related to the 7a-hydroxypyrrolizidine natural products **8**, **9b** and **10**. It is of note that natural product **9a** has hydrogen at the bridgehead position and this presents the intriguing possibility that the jenamidine B₁/B₂ (**9b**) may arise from jenamidine A₁/A₂ (**9a**) through the type of mechanism presented in Scheme 3. Natural products **8** and **10** may have similar origins,³² and we are actively pursuing this possibility.

Current studies in our laboratory are focusing upon the synthesis of hyacinthacine, australine, alexine and castanospermine (and

their epimers), and their **7a-/8a**-hydroxy analogues. A programme of study focused on the synthesis of 8a-hydroxy analogues of the alkylated indolizidines (such as compound **5**) is also underway alongside our continuing studies on the jenamidines.

Acknowledgments

This work was supported by the University of Huddersfield Studentships (to V.V.R.K. and M.I.Q.). We thank Dr Neil McLay, University of Huddersfield, for NMR and mass spectroscopic support, Dr Craig Rice, University of Huddersfield, for X-ray crystallographic studies, and the EPSRC national mass spectrometry service, University of Wales, Swansea for HRMS.

27. Products **14a–i** reported in Table 1 all gave satisfactory spectroscopic data (^1H and ^{13}C NMR, IR, mass spectra and HRMS). Typical procedure: A solution of the cyclopropanone **12** in dry MeCN was added dropwise over 1 min. to an equimolar amount of the imine **17–21** in the same solvent at room temperature (commercial diphenylcyclopropanone and phenylcyclopropanone^{16c,22}) or at 0 °C (cyclopropanone²³). The mixture was stirred at room temperature for 4 h or overnight until IR showed the absence of the distinctive cyclopropanone absorbance at $\sim 1840\text{ cm}^{-1}$. The solvent was removed by rotary evaporation and the residual oil was purified by silica gel column chromatography (typically using hexane: EtOAc 4:6). As an example, compound **14i** (0.1480 g) was obtained from mixing imine **21**²¹ (0.3710 g, 0.92 mmol) and cyclopropanone **12c**²³ ($\text{R}^1 = \text{R}^2 = \text{H}$; 0.050 g, 0.92 mmol) in MeCN (10 mL) at 0 °C for 1 h and then warming to room temperature over 4 h. Compound **14i**: IR: ν_{max} (neat, cm^{-1}): 3359 (b, m), 3062 (w), 3031 (m), 2926 (m), 2867 (m), 1688 (s), 1538 (s), 1454 (m), 1362 (m), 1206 (m), 1111 (s), 738 (m), 699 (m); ^1H NMR (500 MHz, CDCl_3), δ_{H} : 3.44–3.47 (1H, ddd, J 7.2, 5.9, 4.7, CHN), 3.53 (1H, dd, J 7.2, 9.4, CHCH_2OBn), 3.58 (1H, dd, J 4.7, 9.4, CHCH_2OBn), 3.82 (1H, d, J 6.8, $\text{C}(\text{OH})\text{CHOBN}$), 3.89 (1H, br s, OH), 4.17 (1H, dd, J 5.9, 6.8, $\text{CH}(\text{CHOBN})_2$), 4.49 (1H, d, J 11.7, OCH_2Ph), 4.51 (1H, d, J 11.9, OCH_2Ph), 4.55 (1H, d, J 11.9, OCH_2Ph), 4.61 (1H, d, J 11.7, OCH_2Ph), 4.66 (1H, d, J 11.7, OCH_2Ph), 4.97 (1H, d, J 11.7, OCH_2Ph), 5.23 (1H, d, J 3.7, $\text{C}=\text{CH}$), 7.17–7.19 (2H, m, ArH), 7.28–7.37 (13H, m, ArH), 7.76 (1H, d, J 3.7, $\text{HC}=\text{C}$); ^{13}C NMR: δ_{C} (125 MHz, CDCl_3): 62.90 (CH), 71.58 (CH_2), 72.50 (CH_2), 73.06 (CH_2), 73.28 (CH_2), 82.00 (CH), 87.07 (CH), 92.02 (C), 102.24 (CH), 127.36 (CH), 127.47 (CH), 127.51 (CH), 127.57 (CH), 127.75 (CH), 128.05 (CH), 128.07 (CH), 128.13 (CH), 128.14 (CH), 136.68 (C), 137.18 (C), 137.30 (C), 168.75 (CH), 201.73 ($\text{C}=\text{O}$); m/z (electrospray) HRMS: calcd for $\text{C}_{29}\text{H}_{29}\text{NO}_5 + \text{Na}^+ = 494.1938$, found: 494.1947 [2 ppm error].
28. Crystallographic data have been deposited at the Cambridge Crystallographic Data Centre as a CIF deposition with file number CCDC 873002. Copies of these data can be obtained free of charge on application to CCDC, 12, Union Road, Cambridge, CB2 1EZ, UK or from http://www.ccdc.cam.ac.uk/data_request/cif.
